

TIDAL MONITORING DATA TO FEBRUARY 2015

Tweed River Mean Low Water Spring (MLWS) tide level varied from a minimum of -0.323 m AHD to a maximum of -0.167 m AHD for the six months September 2014 to February 2015.

This period of analysis was characterised by a mix of oceanic and catchment events. The latter half of the period was heavily influenced by catchment events with 50% above average monthly rainfalls in the system.

Over the last 12 months the Spring Tidal Range has been consistent and there has been little change in the tidal behaviour of the system.

The TRESBP has not had a significant impact on the Lower Tweed River tidal behaviour to February 2015.

The next set of data is due in August 2015 (six months).
